By Deanna Sclar The basic difference between a diesel engine and a gasoline engine is that in a diesel engine, the fuel is sprayed into the combustion chambers through fuel injector nozzles just when the air in each chamber has been placed under such great pressure that it's hot enough to ignite the fuel spontaneously.

The diesel engine (also known as a compression-ignition or CI engine ), named after Rudolf Diesel, is an internal combustion engine in which ignition of the fuel is caused by the elevated temperature of the air in the cylinder

due to the mechanical compression ( adiabatic compression ). This contrasts with spark-ignition engines such as a petrol engine ( gasoline engine) or gas engine (using a gaseous fuel as opposed to petrol ), which use a spark plug to ignite an air-fuel mixture.

Diesel engines use compression ignition instead of spark ignition, so they are significantly different. These systems inject an air/fuel mixture into a cylinder, which is then compressed to the point where it gets so hot that it ignites without the need for a spark. Diesel

engine relies on compression-ignition, that is, the rise in temperature that accompanies the rise in pressure within the cylinder is sufficient to ignite the fuel spontaneously.

The ignition system is one of the most important systems used in the I.C engines. The spark-ignition engine requires some device to ignite the compressed air-fuel mixture. The ignition takes place inside the cylinder at the end of the compression stroke. Ignition system serves this purpose.

In a diesel engine, ignition is achieved by compression of air alone. A typical compression ratio for a diesel engine is 20:1, compared with 9:1 for a petrol engine. Compressions as great as this heat up the air to a temperature high
